

TRABAJOS ORIGINALES

A polyherbal remedy used for respiratory affections in Moroccan traditional medicine

Un remedio a base de plantas para las afecciones respiratorias en la medicina tradicional marroquí

RESUMEN

Un estudio etnobotánico llevado a cabo en la región de Ksar Lakbir con el objetivo de catalogar el conocimiento popular en materia de plantas medicinales y preparaciones tradicionales nos permitió conocer la existencia de un remedio tradicional para el tratamiento de afecciones respiratorias. La preparación, compuesta de 70 especies de 37 familias.

PALABRAS CLAVE: Etnobotánica, Marruecos, afecciones respiratorias

ABSTRACT

An ethnobotanical survey undertaken in the Rif, northern region of Morocco since 1992 revealed an original herbal remedy used in Laksar Lakbir district for respiratory ailments (tuberculosis, bronchitis, asthma, pneumonia, cough and colds) made up of 70 plant species from 37 botanical families.

KEY WORDS: Herbal remedies, respiratory ailments, Morocco.

INTRODUCTION

History of the north part of Morocco commonly known as Rif was synonymous of marginalization and lack of economical essential structure. Autochtonous population is berber and their economic activity is based on agriculture and livestock. This activity is complemented by fishing and *Cannabis* crops production.

At a time a small number of ethnobotanical reports was published about this zone. A survey in different Rifian areas (North of Morocco, from Oujda to Tanger) has been undertaken by authors to collect information about their medicinal flora. So far around 500 plant specimen have been collected. Results were partly published, concerning medicinal plants

used in Bouhmed district and Ksar Lakbir city (Merzouki et al., 1999; Merzouki et al., 1997b). Different aspects of Rifian *Cannabis* crops were also studied (Merzouki y Molero, 1997a; Merzouki et al., 1996 a; 1996b; Merzouki y Molero, 1995).

In the Rif traditional medicine many species were used for treating common colds, for asthma a particular folk treatment was practiced in Ouazzane district with *Trigonellafoenum-graecum* and *Pistacia lentiscus*.

The present work carried out in Ksar Lakbir district, deals with an original herbal remedy of seventy plant species for treating respiratory ailments

METHODOLOGY

Area of study

Ethnobotanical study was carried out respectively in the district of Jamâat Swaken of Quiadat- Souk Ettolba, situated approximatively 20 Km north of Ksar Lakbir city and in Kabilat ahl Srif and Jamâat Merkad Eddbab of Quiadat Tattouft 15 Km east of Ksar Lakbir city.

With a local population around 5000 persons, data concerning uses of medicinal plants were gathered from direct interviews with informants. Information was obtained through general conversations with 75 group of persons (265 persons, 187 men and 80 women) without asking direct questions. Informants were not scientifically literate and were born in the region. The majority of informants knew an herbal remedy of quack woman (**Haja Rahma**) for treating respiratory ailments. The secret of this preparation belongs to her for more than thirty five years, from the (Aâchab) herbalist of Souss to cure his son who suffered a Tuberculosis. (Souss is a south region of Morrocco which is reputated by their herbalists).

Botanical composition of an herbal remedy

A voucher herbarium specimen were prepared and deposited in the department of Botany, Faculty of Pharmacy, University of Granada. Plant nomenclature was established accordingly to Flore de l'Afrique du Nord (Maire, 1952-1980) Nouvelle Flore de l'Algérie (Quezel and Santa, 1962), Flora Iberica Castroviejo et al., 1986-1997), Flora Europea (Tutin et al., 1964-1980), and Medicinal Plants of North Africa (Boulos, 1983).

Plants were presented with botanical and vernacular names. Ethnobotanical comparation with a bibliographical citation of species was established through consultation of Spanish

ethnoboanical works (Gonzalez Tejero, 1989; Martinez Lirola, 1993; Mulet Pascual, 1991; Perez de Paz y Medina Medina, 1988), North African medicinal plants (Boulos, 1983) Arabian medicinal plants (Ghazanfar, 1994), medicinal plants of the Bible (Duke , 1983), Handbook of medicinal plants (Kapoor, 1990) and phytotochemecodatabase (Beckstrom-Sternberg and Duke, 1987)

Mode of preparation

It's difficult to obtain the secret of traditional phytotherapeutic preparation in Morocco, but from information collected during our investigation we can conclude that approximately four hundred grams plant material were used in this herbal preparation, fifteen litres of water was added in (Borma) a copper pot and placed on a low fire.

Part of plants used were: RO: Root; ST: Stem; LE: Leaf; AP: Aerial part; INF: Inflorescence; SD: Seed; FR: Fruit; FRO: Frond; ST-BR: Stem Bark, BU: Bulb, TH: thalle et FR-EP: Fruit Epicarpe; FL: Flower; Rh: Rhizom.

Mode of Administration

Four litres of filtered decoction were recovered. Administration of the treatment consist in two phases, inhalation and oral:

1- Vapor inhalation: When decoction starts boiling away, patient with head covered on a pot for inhaling vapor.

2- Oral administration: Two daily prises of a coffee cup decoction, first, before breakfast and the second, after dinner.

Treatment period length was variable depending of the affection gravity, from 1 week for treating common colds to four weeks for tuberculosis. During treatment, patient should not eat *citrus* fruits and spicy food.

RESULTS AND DISCUSSION

Socio-economically, Ksar lakbir district is a poor region, rural people lives in precarious conditions, rarity of sanitary structures makes infectious ailments to be present and very frequents. Epidemiological data of 1992 about tuberculosis in Morocco (Laraqui Hassoni y

Belamallem , 1995) reveal that mortality by tuberculosis was around 2.17 for 100000 inhabitants. Incidence of tuberculosis around 30000 cases per year. North-West region of Morocco was the most affected, with 155 cases per 100000 inhabitants. Among sexual prevalence, masculin

sex predomine with 62% in opposit 38% in female sex. In spite of these problems, traditional herbal remedies will continue to be used.

The originality of this herbal remedy resides in the combination of seventy taxa. In Moroccan traditional medicine, polyherbal compositions are quite rare, an exception being represented by **Rass al Hanout** preparation (literally the top of shop) used in Middle East and North of Africa, the Moroccan version of this preparation of thirteen plants was very typical, popularly used in common colds, as aphrodisiac, and for its califacient properties.

The seventy taxa of a respiratory herbal remedy are presented in table 1. The useful plants are distributed among thirty seven families, Angiospermae, thirty three families in which thirteen dicotyldons and three monocotyledons, two pteridophytæ, (Hypolepidiaceæ and Aspleniaceæ), one bryophytæ, (Hypnaceæ) and one lichen (Parmeliaceæ).

Lamiaceæ predominate with ten species, and constitue 14.3% of the total, followed by *Asteraceæ*, *Fabaceæ* and *Cistaceæ* with five species (7.2%) each, *Liliaceæ* four species (5.7%), *Ericaceæ* three species (4.3%), *Apiaceæ*, *Crassulaceæ*, *Lauraceæ*, *Rosaceæ*, *Urticaceæ*, *Zingiberaceæ* and *Graminae* two species (2.9%) each and the other twenty four families were represented by one specie (1.4%) each. Plant samples used for preparing the remedy were generally from aerial part.

The majority of species used in this phytotherapeutic preparation were herbaceous or arbustive and constituted a floristic cortège of *Quercus* formation. Part of plants were introduced (*Zingiber officinale*, *Amomum granum-paradisi*, *Cinnomum zeylanicum*, *Piper nigrum*, *Nigella sativa*) and were purchased from local herbalists and cultivated plants like *Zea mays*, *Punica granatum* and *Opuntia ficus indica*.

Spectrum of species activities, show that fourteen species (17.1%) were previously reported with an activity on respiratory ailments (Bronchitis, Tuberculosis, Asthma, Pneumonia, Cough, colds...). Ten species (14.3%) were cited as analgesic, antiseptic, bactericide, refreshing, sedative or tonic; two species (*Cytinus hypocystis* and *Daphne gnidium*) were cited (Beckstrom and Duke, 1987) as antitumoral. The last twenty species (28.6%) were cited without activity on the respiratory organs. Among these plants, seventeen species were not refered like medicinal plants in bibliographical data cited in this work. These plants are: *Anacyclus radiatus*, *Asparagus aphyllus*, *Asplenium billotii*, *Chamaemelum fuscatum*, *Cytisus villosus*, *Erica terminalis*, *Erica umbellata*, *Eryngium tricuspidatum*, *Halimium halimifolium*, *Hypnum sp.*, *Ononis fruticosa*, *Origanum elongatum*, *Salix pedicellata*, *Sedum brevifolium*, *Stauracanthus boivinii* and *Teucrium fruticans*, however, *Ammomum granum-paradisi* and *Calycotome villosa* were cited by Beckstrom and Duke (1987) with antitumoral activity and *Urtica pilulifera* was catalogued in Andalucian territory (Gonzalez Tejero, 1989) like emollient, cicatrizing and antiemorrhoides.

This traditional herbal remedy for respiratory ailments was apparently efficient, all informants interviewed claimed improvement of patients with the treatment and they had never listened to any patient complication. High percent of informants confirmed the efficiency of a remedy and the very important fact was the low cost of the treatment.

A combination of seventy plants with an important panoply of chemical compounds, show effective and synergic activity and thus a chemical analysis as well as biological essays with a traditional decoction are worthwhile.

ACKNOWLEDGEMENTS

We thank Haja Rahma and all informants who have helped make this study possible In

particular all people of this district who have generously provided the field data here presented.
